Unit 4 - Scheduling and Deadlock

Operating Systems | Semester V | Unit 4 of 5

1. CPU scheduling

FCFS, SJF, priority and round robin. Compare by waiting and turnaround time.
Round robin with a small quantum favours response time over throughput.

2. Deadlock

Four conditions: mutual exclusion, hold and wait, no preemption, circular wait.
Banker's algorithm keeps the system in a safe state before granting a request.

3. Virtual memory

Paging maps virtual pages to frames; the TLB caches recent translations.
Page faults are served by eviction, commonly LRU or the clock algorithm.
